

## FT-IR SPECTROMETER

# INVENIO S

## Technical Specifications

The INVENIO S is a peak performance FT-IR spectrometer focused on maximum productivity in routine and advanced laboratory analysis. Its innovative beam path, and the premium quality of all components, lead to unmatched Mid-IR measurement sensitivity.

The INVENIO S offers unprecedented adaptability for any IR application. Virtually every accessory, from simple to sophisticated, fits into the large sample compartment. Instant switch between measurement techniques is provided by the optional transit channel. External accessories such as the HYPERION microscope or a TGA module can be placed to the left and right of the INVENIO S, widely expanding its capabilities. Optional aluminum optics and in-field upgradability to INVENIO R or X provide access to spectral range expansion and time-resolved spectroscopy. A second detector option provides the optimal detector type for any application.

INVENIO S permanently monitors the instrument configuration, and ensures the device's performance at all times. The long lifetime of all components guarantees permanent availability, best performance, and low running costs of INVENIO S for many years.

OPUS IR spectroscopy software is the user-interface for fast and efficient FT-IR analysis. Workflows dedicated to routine and certain advanced applications guide the operator through the IR analysis. With its comprehensive functionality for spectra processing, qualitative and quantitative evaluation, and reporting OPUS always provides the adequate tools for generating clear results.

Operating INVENIO S by OPUS-TOUCH increases the productivity as measurements and even extensive analytical protocols are accomplished in a rapid and enjoyable way. INVENIO S is compliant for being operated fully validated in regulated environment.

## ● Libraries

Before digital data processing became prevalent, spectra were recorded on paper and compared with analyzed data by hand. Nowadays, digital spectrum collections (libraries) offer a faster, more effective way to compare analysis results. Infrared libraries have been used since the beginning of this digital revolution.

Many infrared libraries are available now, that are categorized by chemical classes, constitution, aggregation state, and even intended use (i.e. environmental protection, homeland defense, etc.)

### **BRUKER databases are designed for use in:**

- Polymers
- Polymer additives
- Fillers
- Inorganic compounds
- Natural fibers
- Synthetic fibers
- Laboratory chemicals
- Vapor-phase compounds
- Drugs
- Kidney stones

Access the largest collection of infrared spectra!

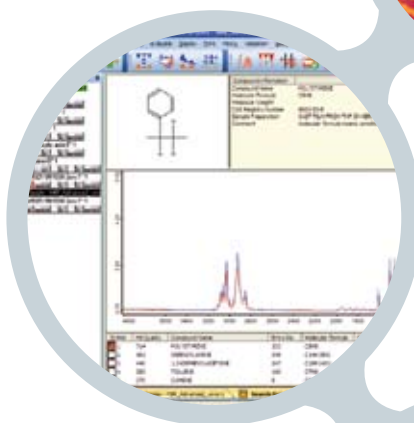

The worldwide digital IR-spectrum collection meanwhile consists of more than 500,000 spectra.

In addition to the spectrum and chemical name, digital databases contain a lot more information on the chemical compound identified, such as structure, CAS identification number, boiling and melting point, and toxicity.

### **Revolutionary search algorithm - having an eye for the essential**

In contrast to the classical approach, Bruker Optics' new algorithm takes the main characteristic of an IR spectrum; the presence of various sharp peaks, into account when comparing a measured infrared spectrum with a database. A unique three level database search compares the peak position, relative intensities and the peak half width. No data pre-treatment has to be used, which makes the algorithm very simple to use. This procedure weights the areas in the spectrum where peaks are present stronger than regions without peaks. This unique algorithm allows to find ATR spectra in transmission libraries and identify components in mixtures.

- Rapid and reliable identification
- Find ATR spectra in transmission databases
- Identify components of mixtures

#### Discovery of infrared light

In the year 1800 the astronomer Friedrich Wilhelm Herschel analyzed the spectrum of sunlight. Herschel created the spectrum by directing sunlight through a glass prism so that the light was divided into its different colors. He measured the heating ability of each color using thermometers with blackened bulbs. When he measured the temperature just beyond the red part of the spectrum he noticed some kind of invisible radiation. Much to his surprise he found that the area close to the red part (i.e. an area apparently devoid of sunlight) had the highest heating ability of all. Herschel concluded that there must be a different kind of light beyond the red portion of the spectrum, which is not visible to the human eye. This kind of light became known as "infrared" (below red) light.

Herschel then placed a water-filled container between the prism and thermometer and observed that the temperature measured was lower than the one measured without the water. Consequently, the water must partially absorb the radiation. In addition, Herschel could prove that depending on how the prism was rotated (i.e. depending on the spectral range) the difference in the temperatures measured for each color varied. This was the beginning of infrared spectroscopy.

Friedrich Wilhelm Herschel  
(1738 - 1822)

Infrared spectroscopy measures the infrared light that is absorbed by a substance. This absorption depends on the wavelength of the light.
